Case study:

A 19 year old girl following a year of limited movement in her left elbow, fixed with a sling at 160 degrees following damage from a fall. Movement is accompanied by grinding sounds and sensitivity throughout the range of movement. The area was treated a year and a half earlier and has not changed. The patient was given chiropractic treatment. From the first treatment it was decided to include treatment with the B-Cure Laser device. It was used to treat the ventrolateral section for 6 minutes. A week later the treatment was repeated a second time and the patient reported significant improvement in the range of movement, so an additional laser treatment was added in conjunction with the previous treatment protocol. Today, a month and a half later, the improvement achieved in just two treatments, has been maintained.

Results:

Complete improvement in the range of movement and reduction of sensitivity to pain for the full length.

Conclusion:

Integrating B-Cure Laser Sport in the clinic for the treatment of old trauma which caused contraction of tendons, muscles and ligaments may be advantageous and offer significant efficacy in shortening the length of treatment.
